PROTECTING SECRET DATA ENTRY FROM INFRARED AND AUDIO EAVESDROPPING

Field of the Invention

This invention relates to methods and systems for protecting secret data entry from infrared and audio eavesdropping.

Background of the Invention

In today's emerging information society, more and more personal and proprietary information is stored in electronic databases. To prevent unauthorized access to these private databases, many electronic systems, computers, and networks require users to enter secret data to initialize a security relationship. While efforts have been made to utilize biological characteristics as secret data, through methods such as voice identification or retinal scanning, widespread use of these methods is years, if not decades, away. The predominant method for providing secret data remains the use of a data entry device, typically a keyboard or keypad, to enter secret data, such as a password or PIN (Personal Identification Number). Entry of the proper secret data initializes a security relationship.

The types of security relationships that are established by means of shared secrets include, but are not limited to, authentication, encryption, and digital signing. In authentication, the possession of the secret verifies the identity of the possessor. In encryption, the secret is used to cryptographically transform a message so it is concealed from third parties but may be transformed back into readable form by one possessing a related secret. In digital signing, a hash is computed over a block of data. The hash is then encrypted with the private cryptographic key of the signer. The signature can be tested by decrypting the signature with the public cryptographic key of the signer and comparing the result to a just-computed hash of the data block.

If these values match, it shows that the signer had the private key corresponding to the public key and also that the data block has not changed.

Authentication credentials are often divided into two parts so that security is not compromised even if one part is lost or stolen. For example, a person wishing to transact business at an Automatic Teller Machine generally identifies himself or herself by presenting an "ATM card" and concurrently entering a string of numbers called a "PIN" (Personal Identification Number) onto a keypad. The "ATM card" bears identifying information, such as an account number, encoded on a magnetic stripe. A person possessing only half of the secret, only the ATM card or only the secret PIN, is not authorized to perform transactions. Similarly, home security systems rely on the authorized entrant to possess both a key to the house and a security system PIN. An authorized entrant generally disables a home security system alarm by using a keypad to enter a secret string of numbers. If a person entering the house fails to enter the correct PIN within a short period of time, the alarm system may automatically summon law enforcement personnel to apprehend the unauthorized person.

While many systems divide authentication credentials into a tangible object and a password or PIN, many systems rely solely on a password or PIN for authentication. For example, new short-range wireless data communications systems, such as the Bluetooth standard, use a PIN to generate a link key. The link key serves for authentication and encryption allowing secure communication between a pair of devices. Similarly, passwords are commonly used to secure access to computers and networks. For systems that rely entirely on a password or PIN for authentication, the security of the entire system may be adversely affected if the password or PIN is lost, stolen, or otherwise compromised.

A password or PIN may be stolen in several ways including detecting the keypad or keyboard using a physical sensor while the user enters his or her password or PIN or tapping into the electrical circuit or network downstream from the keypad or keyboard to capture the password or PIN after the user has entered it into the keypad or keyboard. Previous efforts have been focused on protecting PINs and passwords from this latter form of compromise; however, little work has focused on detection of secret data entry by physical sensors.

One way to steal a password or PIN using a physical sensor is to observe the keypad or keyboard as the user enters his or her PIN or password. This observation may be performed either visually or by means of an optical device such as a camera. Structures designed to prevent this type of monitoring are described in U.S. Patent 5,748,728 to Ginsberg et al. entitled "*Shield for Concealing Operation of a Keypad*". These structures may have provided some protection of passwords and PINS when the eavesdropping threat was limited to optical sensors. However, such simple security measures are increasingly ineffective as new highly-sophisticated physical sensors become readily available. This new breed of physical sensors includes devices that detect infrared signatures as well as refined audio sensors.

Devices that create images by detecting the infrared portion of the electromagnetic spectrum are well-known. These devices typically have been used in the public sector as military and police personnel may often use them to image human beings and structures in low-light conditions. Rescue workers use these devices in search-and-rescue operations to locate persons trapped in damaged buildings. Firemen use them to locate hot spots in burning buildings. Additionally, infrared-imaging devices are used routinely for medical diagnostic purposes to image the human body and differentiate between body areas of normal temperature and those with abnormal temperature, which might indicate a disease process, injury, or the like. Some infrared detectors are so sensitive that they can image, for example, footprints in the ground, by discerning the slight difference between the average background temperature and a temperature that is slightly elevated as a result of human contact.

An eavesdropper could use a sensitive infrared-imaging device to inspect a keyboard or keypad shortly after a person has entered a secret such as a PIN thereon. The eavesdropper would prefer to perform the imaging after the person entering the PIN has left the area in order to remain undetected by the person entering the PIN. The infrared-imaging device would be used to create an image of the heat signature on the keypad. The heat signature on the keys most recently touched would be slightly more intense than those touched earlier in the PIN sequence. By comparing the temperature values for the keys and arranging them in sequence from the coolest to the warmest, the eavesdropper could form a strong hypothesis about the sequence in which the keys were touched.

For example, Figure 1 shows a conventional data entry device as detected using an infrared-imaging device. In this figure, the data entry device **10** is a keypad with keys **11** on it. This image of the keypad is taken immediately after a user has entered his or her PIN. In the image, the background temperature is represented by white. Temperatures above the background temperature are represented by varying shades of gray with black being the hottest temperature. As shown in Figure 1, the 6 key is the darkest shade of gray. The 5 key is a slightly lighter shade of gray. The 2 key is lighter still. Finally, the 1 key is the lightest shade of gray. Thus, the 1 key is the coolest and the 6 key is the warmest. Now arranging the keys in order from coolest to warmest, the eavesdropper learns that the user's PIN is 1-2-5-6. Depending on the accuracy of the temperature data, infrared imaging may immediately and unequivocally reveal the PIN. Even if the shades of gray are very close together, this imaging greatly reduces the number of combinations that must be tried to learn the secret PIN. For example, if the shades of gray in Figure 1 had been indiscernible, the use of imaging would still have reduced the number of combinations that the eavesdropper must try from 10,000 to 24.

One way of thwarting infrared detection is to require that PIN numbers include one or more repeated digits. Keys that are touched more than once are likely to be warmer than would otherwise be the case. For example, if a PIN number were 1223, the heat signature would likely show that the 2 key is the warmest since it was touched twice, followed by the 3 key, with the 1 key being the coolest. Thus, an eavesdropper would incorrectly surmise that the PIN was 231. However, if the eavesdropper realized that the PIN contained four digits, knowing in advance that all PIN numbers have one or more repeated digits would merely reduce the number of combinations that must be tried. As a result, this method of thwarting infrared detection would actually reduce the PIN's effectiveness as a secret. Therefore, a strong need exists for a way of thwarting infrared detection of secret data entered into data entry devices without reducing the data's effectiveness as a secret.

Aside from infrared-imaging devices, eavesdroppers could use refined audio sensors to discover secret data, such as a PIN or password, without resorting to direct observation. To discover a PIN, an eavesdropper might place a hidden microphone attached to a recording device in position to detect sound generated by entering data into a data entry device. The eavesdropper could then subject the recorded sound to a

sensitive analysis, such as a Fourier transform, of the audio spectrum associated with pressing each key on a keyboard or keypad. This analysis may yield a distinctive, repeatable audio signature for each key. Such analysis is now increasingly possible with the computing-power of ordinary, inexpensive personal computers. Each key
5 may have a different audio signature based on its physical characteristics and its physical location. The physical characteristics of each key will be different for a number of reasons. Different physical characteristics occur as part of the manufacturing process. Each key is manufactured within relatively imprecise tolerances such that there is an extremely small likelihood that two keys on the same
10 keypad are exactly alike. Additionally, over time the striking surfaces of the keys on a keypad experience varying degrees of wear. This non-uniform wear contributes to distinct audio signatures for each key on the keypad. The physical location of each key on the keypad also contributes to distinct audio signatures for each key. Since each key is physically located in a different place on the keypad, any echoes from
15 nearby objects, such as a shield around the keypad of an ATM machine, may be different for each key pressed. This difference occurs as a result of sound waves bouncing off nearby reflectors at different angles and travelling different distances prior to reaching the microphone. This audio spectrum information, either alone or in combination with the aforementioned infrared imaging means, may yield a very high
20 probability of uncovering a secret PIN without direct visual or optical observation of entry.

Summary of the Invention

It is therefore an object of the present invention to provide methods and
25 systems for protecting secret data entry from infrared eavesdropping.

It is another object of the present invention to provide methods and systems for protecting secret data entry from audio eavesdropping.

These and other objects are provided, according to the present invention, by a method for protecting a data entry device from eavesdropping that includes masking a
30 signature of entry resulting from entry of data by a user of the data entry device so as to reduce the detectability of the signature by eavesdropping.

According to the present invention, the signature may include a temperature differential in the data entry device from data entry by the user and the masking may

include controlling the external temperature of the data entry device to reduce temperature differentials left in the data entry device by the user.

5 In a preferred embodiment, controlling the external temperature of the data entry device includes maintaining the external temperature in a range surrounding a predetermined setpoint. The predetermined setpoint may be between about 35-40°C. By controlling heating and cooling, the temperature differentials in a data entry device that a user creates by entering data into the device may be reduced such that these temperature differentials are less detectable by an infrared-imaging device.

10 According to the present invention, the signature may also include sound waves emitted from the data entry device and the masking may also include masking sound waves emitted from the data entry device to reduce the detectability of the sound waves.

15 In a preferred embodiment, the masking of sound waves includes generating an interfering sound pattern so as to reduce the detectability of the sound waves. Generating the interfering sound pattern includes receiving the signature, converting the signature to an electrical signal, phase-shifting the electrical signal, converting the phase-shifted electrical signal to an audio signal, and emitting the audio signal in close proximity to the data entry device. By providing an interfering sound pattern, the sound waves created by data entry into a data entry device may be masked to
20 reduce the detectability of the sound waves by audio eavesdropping.

According to the present invention, a system may also be employed for protecting data entry to a data entry device from eavesdropping. The system includes a data entry device and a means for masking a signature of entry resulting from entry of data by a user of the data entry device so as to reduce the detectability of the
25 signature by eavesdropping.

In a preferred embodiment, the means for masking includes a means for establishing the external temperature of the data entry device to reduce temperature differentials left in the data entry device by the user.

30 In another preferred embodiment, the means for masking includes a means for masking sound waves emitted from the data entry device to reduce the detectability of the sound waves.

Methods and systems according to the present invention may therefore protect secret data entry into a data entry device by a user from infrared and audio

eavesdropping. It will be understood that the present invention may be embodied as methods and systems and combinations thereof.

Brief Description of the Drawings

5 Figure 1 illustrates a conventional data entry device immediately after use by a user.

 Figure 2 illustrates a conventional data entry device immediately after use by a user after employing the present invention.

10 Figure 3 illustrates a temperature feedback control circuit according to the present invention.

 Figure 4 illustrates a system for providing resistive heat to a data entry device according to the present invention.

 Figure 5 illustrates a system for providing convective heat in proximity to a data entry device according to the present invention.

15 Figure 6 illustrates a system for radiating heat in proximity to a data entry device according to the present invention.

 Figure 7 illustrates a noise cancellation circuit according to the present invention.

20 Figure 8 illustrates a system for providing an interfering sound pattern using a sound generator according to the present invention.

Detailed Description of Preferred Embodiments

 The present invention now will be described more fully hereinafter with reference to the accompanying drawings, in which preferred embodiments of the invention are shown. This invention may, however, be embodied in many different
25 forms and should not be construed as limited to the embodiments set forth herein; rather, these embodiments are provided so that this disclosure will be thorough and complete, and will fully convey the scope of the invention to those skilled in the art. Like numbers refer to like elements throughout.

30 Figure 2 shows a data entry device **10** that utilizes keys **11** for data entry. In Figure 2, the assumption has been made that background temperature is less than the temperature of the user. The keys **11** have been heated above background temperature so as to mask any temperature differential that might be created in the

keys 11 when a user utilizes them to enter data into the data entry device 10. This masking reduces the infrared detectability of the data entered into the data entry device 10. Of course if the background temperature were hotter than the temperature of the user, the keys 11 could be cooled to mask any temperature differential that might be created in the keys 11 when the user enters data into the data entry device 10. Various systems for masking temperature differentials in data entry devices to reduce infrared detectability are described in Figures 3-6.

Referring now to Figure 3, a feedback control circuit of the present invention will now be described. A temperature sensor 30 is operably associated with a data entry device 10. The temperature sensor 30 measures the temperature of the external surface of the data entry device 10. The temperature sensor 30 is also operably associated with a control circuit 31, which is operably associated with a heating/cooling device 32. The data entry device 10 may be a keypad, a keyboard, a touch-tone phone, or any other known data entry device. The temperature sensor 30 may conveniently be a thermocouple or any other known temperature-sensing device. The heating/cooling device 32 may be a resistive heating element, an infrared emitting lamp, a blower, or any other known means for providing cooling or heating to a data entry device.

Still referring to Figure 3, the temperature sensor 30 provides the control circuit 31 with the external temperature of the data entry device 10. The control circuit 31 compares the external temperature of the data entry device 10 as measured by the temperature sensor 30 with a predetermined setpoint. If the external temperature of the data entry device 10 as measured by the temperature sensor 30 is higher than the predetermined setpoint, the control circuit 31 sends a signal to the heating/cooling device 32 directing it to cool the data entry device 10. This cooling continues until the external temperature of the data entry device 10 as measured by the temperature sensor 30 equals the predetermined setpoint. At that time, the control circuit 31 sends a signal to the heating/cooling device 32 directing it to stop cooling the data entry device 10. Similarly, if the external temperature of the data entry device 10 as measured by the temperature sensor 30 is lower than the predetermined setpoint, the control circuit 31 sends a signal to the heating/cooling device 32 directing it to heat the data entry device 10. This heating continues until the external temperature of the data entry device 10 as measured by the temperature sensor 30

equals the predetermined setpoint. At that time, the control circuit 31 sends a signal to the heating/cooling device 32 directing it to stop heating the data entry device 10. Suitable control circuits for carrying out temperature feedback control are known to those of skill in the art and need not be described further herein.

5 While Figure 3 illustrates a feedback control system, as will be appreciated by those of skill in the art, an open loop system may also be utilized. Thus, for example, a heating source may be continuously operated. Also, while the present invention is described in Figure 3 as both heating and cooling, as will be appreciated by those of skill in the art, only one of heating or cooling may be needed. Thus, the present
10 invention should not be construed as limited to both heating and cooling.

Referring now to Figure 4, a system for resistively heating a data entry device 10 of the present invention so as to reduce temperature differentials left in the data entry device by the user will now be described. Keys 11 reside on a data entry device 10. A resistive heating element 40 also resides on the data entry device 10 such that
15 the resistive heating element 40 provides heat to the keys 11 when an electrical current is applied to the resistive heating element. The resistive heating element 40 may conveniently be a resistive pattern of wires surrounding the keys 11. The resistive heating element 40 could also be a resistive layer formed as part of a data entry device 10, which is formed using methods such as those described in U.S.
20 Patent No. 5,828,016 to Grannan et al. entitled "*Low Profile Tactile Switch*", the disclosure of which is incorporated herein by reference. The keys 11 could be constructed from a thermally conductive material such as aluminum, copper, nickel, or any other thermally conductive material. Alternatively, the keys 11 could be plated with a thermally conductive material such as aluminum, copper, nickel, or any other
25 thermally conductive material.

Referring now to Figure 5, a system for heating or cooling a data entry device 10 by convection will now be described. A blower 50 directs a stream of air 51 in close proximity to a data entry device 10. The stream of air 51 may be temperature-controlled such that it is hotter or cooler than the data entry device 10. The stream of
30 air 51 may blow directly on the data entry device 10, thus heating or cooling the surface of the data entry device 10. Heating the device using the stream of air may reduce the temperature differentials in the data entry device created when a user enters data into the device. Alternatively, or concurrently, the stream of air 51 could

be directed so as to form a thermal curtain in front of the data entry device 10. The thermal curtain could mask temperature differentials created when a user enters data into the data entry device 10 by forming a thermal barrier in front of the data entry device 10. If an eavesdropper attempted to image the data entry device 10 with an infrared-imaging device, the thermal barrier would create an image on the device that masks the image of the data entry device 10. As viewed using the infrared-imaging device, the thermal barrier may appear to be a substantially opaque curtain draped in front of the data entry device 10.

Referring now to Figure 6, a system for heating a data entry device 10 by radiation will now be described. An infrared emitting lamp 60 is operably associated with a data entry device 10. The infrared emitting lamp 60 radiates heat 61 in proximity to the data entry device 10. The infrared emitting lamp 60 may radiate directly onto the data entry device 10, thus heating the surface of the data entry device 10. Alternatively, or concurrently, the infrared emitting lamp 60 may radiate in front of the data entry device 10 forming a thermal curtain in front of the data entry device 10. As with the stream of air, the thermal curtain could mask temperature differentials created when a user enters data into the data entry device 10 by forming a thermal barrier in front of the data entry device 10. If an eavesdropper attempted to image the data entry device 10 with an infrared-imaging device, the thermal barrier would create an image on the device that masks the image of the data entry device 10. As viewed using the infrared-imaging device, the thermal barrier may appear to be a substantially opaque curtain draped in front of the data entry device 10.

The foregoing Figures and descriptions have shown how the present invention can be used to reduce temperature differentials left in a data entry device when a user enters data into the device. However, the present invention is not limited to protecting data entry to a data entry device from thermal eavesdropping. The present invention also is directed to protecting data entry to a data entry device from audio eavesdropping. Various systems for masking sound waves created by data entry into data entry devices to reduce audio detectability are described in Figures 7-8.

Referring now to Figure 7, a system for canceling the sound waves produced by entering data into a data entry device 10 will be described. A sensitive microphone 70 is operably associated with a data entry device 10. The sensitive microphone 70 receives sound waves produced by the entering of data into a data entry device 10 by

a user. The sensitive microphone 71, which is also operably associated with a noise cancellation circuit 71, converts the sound waves to an electrical signal and sends the electrical signal to the noise cancellation circuit 71. After receiving the electrical signal, the noise cancellation circuit 71 shifts the phase of the electrical signal, preferably by 180°. The phase-shift may be accomplished in real time using an adaptive digital signal processor such as those known to those skilled in the art. The processor delays components of the audio spectrum by one-half wavelength so that they are out of phase with the audio inputs. Then, the noise cancellation circuit 71 sends the phase-shifted electrical signal to a speaker 72. The speaker 72 is located in close proximity to the data entry device 10. The speaker 72 converts the phase-shifted electrical signal to an audio signal. The speaker then emits sound waves 73 corresponding to the audio signal. The emitted sound waves 73 may be substantially 180° out of phase with the sound waves produced by the entry of data into the data entry device 10 by a user. Thus, the emitted sound waves 73 may substantially cancel the produced sound waves such that the operation of the keys on the data entry device may be undetectable by a listening device or have insufficient level to be differentiated from each other or background noise.

Referring now to Figure 8, a system for providing an interfering sound pattern using a sound generator will be described. A sound generator 80 is operably associated with a speaker 81, which is operably associated with a data entry device 10. In a preferred embodiment, the sound generator 80 generates an electrical signal corresponding to pre-recorded sounds. The pre-recorded sounds are recorded sounds of random input to the data entry device 10. The sound generator 80 sends the electrical signal to the speaker 81. The speaker 81 converts the electrical signal to an audio signal and emits sound waves 82 corresponding to the audio signal in proximity to the data entry device 10. By generating an interfering sound pattern, the operation of the keys on the data entry device may be undetectable by a listening device or have insufficient level to be differentiated from each other or background noise.

In the drawings and specification, there have been disclosed typical preferred embodiments of the invention and, although specific terms are employed, they are used in a generic and descriptive sense only and not for purposes of limitation, the scope of the invention being set forth in the following claims.

What is Claimed is:

1. A method for protecting data entry to a data entry device from eavesdropping comprising the steps of:

masking a signature of entry resulting from entry of data by a user of the data entry device so as to reduce the detectability of the signature by eavesdropping.

2. A method according to Claim 1

wherein the signature comprises a temperature differential in the data entry device from data entry by the user, and

5 wherein the step of masking comprises controlling the external temperature of the data entry device to reduce temperature differentials left in the data entry device by the user.

3. A method according to Claim 1 wherein the data entry device is a keyboard.

4. A method according to Claim 1 wherein the data entry device has external surfaces that are thermally conductive.

5. A method according to Claim 1 wherein the data entry device has external surfaces that are thermally resistive.

6. A method according to Claim 2 wherein the step of controlling comprises the step of maintaining the external temperature in a range surrounding a predetermined setpoint.

7. A method according to Claim 6 wherein the step of maintaining the external temperature comprises the steps of:

monitoring the external temperature of the data entry device to provide a device temperature, and

5 adjusting the output of a temperature control mechanism responsive to the device temperature so as to maintain the device temperature at approximately the setpoint.

8. A method according to Claim 6 wherein the predetermined setpoint is between 35-40°C.

9. A method according to Claim 2 wherein the controlling step comprises the step of controlling the external temperature utilizing conduction.

10. A method according to Claim 2 wherein the controlling step comprises the step of controlling the external temperature utilizing convection.

11. A method according to Claim 10 wherein the step of controlling the external temperature utilizing convection comprises blowing a stream of temperature-controlled air in proximity to the data entry device.

12. A method according to Claim 2 wherein the controlling step comprises the step of controlling the external temperature utilizing radiation.

13. A method according to Claim 12 wherein the step of controlling the external temperature utilizing radiation comprises emitting heat from an infrared-emitting lamp in proximity to the data entry device.

14. A method according to Claim 1 wherein the signature comprises sound waves emitted from the data entry device, and

5 wherein the step of masking comprises masking sound waves emitted from the data entry device to reduce the detectability of the sound waves.

15. A method according to Claim 14 wherein the step of masking sound waves comprises generating an interfering sound pattern so as to reduce the detectability of the sound waves.

16. A method according to Claim 15 wherein the step of generating comprises the steps of:

- 5 receiving the signature,
converting the signature to an electrical signal,
phase-shifting the electrical signal,
converting the phase-shifted electrical signal to an audio signal, and
emitting the audio signal in close proximity to the data entry device.

17. A method according to Claim 15 wherein the step of generating comprises emitting pre-recorded sounds.

18. A method according to Claim 17 wherein the pre-recorded sounds are recorded sounds of random input to the data entry device.

19. A method according to Claim 15 wherein the step of generating comprises providing background noise to mask the sound waves emitted from the data entry device.

20. A method according to Claim 19 wherein the background noise is provided by a blower.

21. A method according to Claim 20 wherein the blower blows a stream of temperature-controlled air in proximity to the data entry device controlling the external temperature of the data entry device to reduce temperature differentials left in the data entry device by the user.

22. A method according to Claim 14 wherein the step of masking comprises providing a sound-dampening device on the data entry device.

23. A system for protecting data entry to a data entry device from eavesdropping comprising:
a data entry device, and

means for masking a signature of entry resulting from entry of data by a user
5 of the data entry device so as to reduce the detectability of the signature by
eavesdropping.

24. A system according to Claim 23 wherein the data entry device is a
keyboard.

25. A system according to Claim 23 wherein the means for masking
comprises means for establishing the external temperature of the data entry device to
reduce temperature differentials left in the data entry device by the user.

26. A system according to Claim 25 wherein the means for establishing
comprises a resistive heating source operably associated with the data entry device so
as to maintain the external temperature in a range surrounding a predetermined
setpoint.

27. A system according to Claim 26 wherein the resistive heat source
comprises a heating element formed as part of the data entry device.

28. A system according to Claim 25 wherein the means for establishing
comprises a radiant heat source operably associated with the data entry device so as to
maintain the external temperature in a range surrounding a predetermined setpoint.

29. A system according to Claim 28 wherein the radiant heat source
comprises an infrared emitting lamp which radiates heat in proximity to the data entry
device.

30. A system according to Claim 25 wherein the means for establishing
comprises a convection heat source operably associated with the data entry device so
as to maintain the external temperature in a range surrounding a predetermined
setpoint.

31. A system according to Claim 30 wherein the convection heat source comprises a blower which provides a stream of air in proximity to the data entry device.

32. A system according to Claim 23 wherein the means for masking comprises a feedback control circuit which provides a closed loop feedback control of the temperature wherein the feedback control circuit comprises:

5 a temperature sensor operably associated with the data entry device so as to measure the external temperature of the data entry device, and

a control circuit operably associated with the temperature sensor and with means for controlling temperature so as to control the means for establishing the external temperature of the data entry device based on the sensed temperature.

33. A system according to Claim 23 wherein the means for masking comprises means for masking sound waves emitted from the data entry device to reduce the detectability of the sound waves.

34. A system according to Claim 33 wherein the means for masking sound waves comprises means for generating an interfering sound pattern so as to reduce the detectability of the sound waves.

35. A system according to Claim 34 wherein the means for generating comprises a noise cancellation circuit which cancels the sound waves emitted by the data entry device wherein the noise cancellation circuit comprises:

5 a microphone operably associated with the data entry device so as to receive sound waves from the entry of data by a user into the data entry device,

a first converting means operably associated with the microphone so as to convert the sound waves into an electrical signal,

10 a phase-shifting means operably associated with the first converting means so as to shift the phase of the electrical signal to produce a phase-shifted electrical signal,

a second converting means operably associated with the phase-shifting means so as to convert the phase-shifted electrical signal to an audio signal, and

an emitting means operably associated with the second converting means so as to emit the audio signal in close proximity to the data entry device.

36. A system according to Claim 34 wherein the means for generating comprises a sound generator operably associated with the data entry device so as to generate an interfering sound pattern so as to reduce the detectability of the sound waves.

37. A system according to Claim 36 wherein the sound generator comprises a speaker which emits pre-recorded sounds.

38. A system according to Claim 37 wherein the pre-recorded sounds are recorded sounds of random input into the data entry device.

39. A system according to Claim 36 wherein the sound generator comprises a blower which disrupts the sound waves by blowing a stream of air in proximity to the data entry device.

PROTECTING SECRET DATA ENTRY FROM INFRARED AND AUDIO EAVESDROPPING

Abstract of the Invention

A method for protecting a data entry device from eavesdropping includes masking a signature of entry resulting from entry of data by a user of the data entry device so as to reduce the detectability of the signature by eavesdropping. The
5 signature may include a temperature differential in the data entry device from data entry by the user and the masking may include controlling the external temperature of the data entry device to reduce temperature differentials left in the data entry device by the user. Alternatively, the signature may include sound waves emitted from the data entry device and the masking may include masking sound waves emitted from
10 the data entry device to reduce the detectability of the sound waves. A system may also be employed for protecting data entry to a data entry device from eavesdropping. The system includes a data entry device and means for masking a signature of entry resulting from entry of data by a user of the data entry device so as to reduce the detectability of the signature by eavesdropping.

DECLARATION AND POWER OF ATTORNEY FOR PATENT APPLICATION

Attorney Docket No. 5577-175

As a below named inventor, I hereby declare that:

My residence, post office address and citizenship are as stated below next to my name.

I believe I am the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled

PROTECTING SECRET DATA ENTRY FROM INFRARED AND AUDIO EAVESDROPPING,

the specification of which

☒ [X] is attached hereto

OR

☐ [] was filed on _____ as United States Application No. or PCT International Application Number _____ and was amended on _____ (if applicable).

I hereby state that I have reviewed and understand the contents of the above-identified specification, including the claims, as amended by any amendment referred to above.

I acknowledge the duty to disclose information which is material to patentability as defined in Title 37 Code of Federal Regulations, § 1.56.

I hereby claim foreign priority benefits under Title 35, United States Code, § 119(a)-(d) or § 365(b) of any foreign application(s) for patent or inventor's certificate, or § 365(a) of any PCT International application which designated at least one country other than the United States of America, listed below and have also identified below any foreign application for patent or inventor's certificate, or of any PCT International application having a filing date before that of the application on which priority is claimed.

ENGLISH LANGUAGE DECLARATION CONTINUED

I hereby claim the benefit under Title 35, United States Code, § 119(e) of any United States provisional application(s) listed below.

None	
Application Number(s)	Filing Date (MM/DD/YYYY)
Application Number(s)	Filing Date (MM/DD/YYYY)

I hereby claim the benefit under Title 35, United States Code, § 120 of any United States application(s) or § 365(c) of any PCT international application designating the United States of America, listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in the prior United States or PCT International application(s) in the manner provided by the first paragraph of Title 35, United States Code, § 112, I acknowledge the duty to disclose information which is material to patentability as defined in Title 37, Code of Federal Regulations, § 1.56 which became available between the filing date of the prior application and the national or PCT international filing date of this application (37 C.F.R. § 1.63(d)).

None		
Appln. Serial No.	Filing Date	Status Patented/Pending/Abandoned
Appln. Serial No.	Filing Date	Status Patented/Pending/Abandoned
Appln. Serial No.	Filing Date	Status Patented/Pending/Abandoned

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of the application or any patent issued thereon.

ENGLISH LANGUAGE DECLARATION CONTINUED

POWER OF ATTORNEY: As a named inventor, I hereby appoint the following registered attorney(s) to prosecute this application and transact all business in the Patent and Trademark Office connected therewith.

A. Bruce Clay
Registration No. 32,121

Edward H. Duffield
Registration No. 25,970

Gregory M. Doudnikoff
